

Number Base Case
N = d_n R^n + d_1 R^1 + d_0 R^0
the d specifies the Number system -> d_2 == binary
can also be written as R_2
This can also be used to expand numbers:
N_10255 = 2 * 10^2 + 5 * 10^1 + 5 * 10^0
N_2110 = 1 * 2^2 + 1 * 2^1 + 0 * 2^0 => N_106

Quantities:
N -> natural numbers || Z -> full numbers
Q -> rational numbers || R -> real numbers

Common number systems:
Decimal: N_10 = n * 10^n .. 0 * 10^0
Binary: N_2 = n * 2^n .. 0 * 2^0
2^10 = 1024, 2^9 = 512, 2^8 = 256, 2^7 = 128, 2^6 = 64,
2^5 = 32, 2^4 = 16, 2^3 = 8, 2^2 = 4, 2^1 = 2, 2^0 = 1
Hexadecimal: N_16 = n * 16^n .. 0 * 16^0
notation: 0 1 2 3 4 5 6 7 8 9 A B C D E F
16^5 = 1048576, 16^4 = 65536, 16^3 = 4096, 16^2 = 256,
16^1 = 16, 16^0 = 1

Modulo
8 mod 4 = (8) -> 0, 8 mod 3 = (6) -> 2, 8 mod 5 = (5) -> 3
if x < y in x mod y then the result will always be x!
any negative numbers can be considered as NOTnegative
aka only absolute values! modulo deals with |x|
many programming languages actually do not follow this!
they have their own implementation of modulo.
5 ≡ 3 mod 2 -> as 5 mod 2 = 1 and 3 mod 2 = 1

Codeword length
Byte = 8 bit || Word = 16 or 32 bit
TCP packet = 1024 bit

Cyclic group
Es sei F(a) = a^3 + a + 1 = 0,
■ Dann können wir zunächst festhalten
■ a = a
■ a^2 = a^2 aber
■ a^3 = a + 1
■ a^4 = a(a + 1) = a^2 + a
■ a^5 = a(a^2 + a) = a^3 + a^2 = a^2 + a + 1
■ a^6 = a(a^2 + a + 1) = a^3 + a^2 + a = a + 1 + a^2 + a = a^2 + 1
■ a^7 = a(a^2 + 1) = a^3 + a = a + 1 + a = 1
■ a^8 = a : der Zyklus beginnt von vorne!
■ {0, 1, a, a^2, a+1, a^2 + a, a^2 + a+1, a^2 + 1}
■ {000, 001, 010, 100, 011, 110, 111, 101}

WHAT THE FUCK
Result Quantity the result of all possible outcomes
it is denoted with: Ω
A single element of the result list is: ω -> ω ∈ Ω
The list of results is |Ω|
Example Dice roll: Ω = {1, 2, 3, 4, 5, 6}

Probability: P(A) = best results / all results = |A| / |Ω| = |A| / n
So what is the probability of rolling a 6?
P(desired number to roll) = only 1 good result! / 6 possible results = 1 / 6
hence the chance is 1 in 6
Why this complicated method? You can modify desired results!
just change the A in P(A)!

Inverse Probability: P(Inverse) = 1 - P(A)
dice -> 1 - 1/6 = 5/6

Addition rule:
P(A ∪ B) = P(A) + P(B) - P(A ∩ B)
!!The last part is needed, as otherwise the number
would exceed the possible states!!
P(A ∪ B ∪ C) = P(A) + P(B) + P(C) - P(A ∩ B) - P(A ∩ C)
- P(B ∩ C) + P(A ∩ B ∩ C)

Amount of possibilities:
ordered probes with replication:
2 coins, head and tail, possibilities? k=head/tail=2 n=coins=2
Ω = n^k = 2^2
ordered probes without replication:
5 dices. How many combinations?
dice numbers = n = 6 (1-6), dice amount = k = 5
possibilities = Ω = n! / (n - k)! = Ω = 6! / (6 - 5)! = 720
Or this:
Ω = Π_{n-k+1}^n = Π_{6-5+1}^6 = 2 * 3...5 * 6 = 720
unordered probes without replication:
25 players, each should play once with the other.
Ω = n! / k!(n - k)! -> 25! / 2!(25 - 2)! = too big = 300
as you can see the bottom is a BIG calculation, so
Ω = Π_{n-k+1}^n -> Π_{25-2+1}^{25} -> 24 * 25 / 2 = 300
Note that k can also be defined as the
length of the tuple we want to receive.
-> (Player, Player) -> 2

Source to Sink Information

Nachricht (Darstellung & Bedeutung)	redundant	nicht-redundant
irrelevant	Zeichenvorrat bei Quelle und Senke verschieden	
relevant	vorhersagbar	Information

Entropy
information content
this essentially just us how many bits are needed
k is base state count -> bit = 2
and N is the full number of states
example: list True,False,True,False 4 states total, base 2.
H_0 = log_k(N)[k] -> H_0 = log_2(4)[bit] = 2

information flow
essentially information content over time
H_0^* = log_2(N) [bit / s]
information quantity
I(x_k) = -log_2(P(x_k))[bit]
Entropy
Probability * information content
H(X) = Σ_{k=1}^N P(x_k) * I(x_k) [bit / symbol]
where X is the list of symbols
Sink Redundance / Code Redundance
R_Q = H_0 - H(X) [bit / symbol]
R_c = L - H(X) [bit / symbol]
Code Word Length
L(x_k) = rounded(I(x_k))[bit]
Median Code Word Length
L = Σ_{k=1}^N P(x_k) * L(x_k) [bit / symbol]
Entropy of the entire Code
H_c(X) = Σ_{k=1}^N P(x_k) * L(x_k) [bit / symbol]
H_c can be a real number -> H_c ∈ ℝ

Für jede beliebige zugehörige Binärcodierung mit Präfixeigenschaft ist die mittlere Codewortlänge nicht kleiner als die Entropie H(X):
H(X) ≤ L
Für jede beliebige Quelle kann eine Binärcodierung gefunden werden, so dass die folgende Ungleichung gilt:
H(X) ≤ L ≤ H(X) + 1

Sink without memory
P(x_k, y_k) = P(x_k) + P(y_i)
Sink with memory
P(x_k, y_i) = P(x_k) + P(x_k | y_i)
Entropy without memory
H(H, Y) = Σ_{x_k} Σ_{y_i} P(x_k, y_i) * (-log_2(P(x_k, y_i)))
Entropy with memory
H(H, Y) = Σ_{x_k} Σ_{y_i} P(x_k) * P(x_k, y_i) * (-log_2(P(x_k) * P(x_k | y_i)))

Encoding of Symbols
• Ordne die Zeichen gemäss ihrer Auftretenswahrscheinlichkeit
• Die beiden Zeichen mit der kleinsten Auftretenswahrscheinlichkeit haben die gleiche CW-Länge L_N
• Sei L_N die mittlere CW-Länge für eine Quelle mit N Zeichen und L_{N-1} die mittlere CW-Länge für den Fall, dass die beiden letzten zu einem einzigen Zeichen zusammengefasst werden, dann gilt:
L_N - (p(x_{N-1}) + p(x_N)) * L(x_{N-1} + p(x_N)) = L_{N-1} - (p(x_{N-1}) + p(x_N)) * (L(x_N) - 1)
⇒ L_N = L_{N-1} + p(x_{N-1}) + p(x_N)

1	2	3	4	5	6	7	8	9
0.22	0.19	0.15	0.12	0.08	0.07	0.07	0.06	0.04
1	2	3	4	8	9	5	6	7
0 1								
0.22	0.19	0.15	0.12	0.1	0.08	0.07	0.07	
1	2	3	6	7	4	8	9	5
0				1	0 1			
0.22	0.19	0.15	0.14		0.12	0.1	0.08	
1	2	8	9	5	3	6	7	4
00		01	1	0 1				
0.22	0.19	0.18			0.15	0.14	0.12	

continue this pattern until every symbol has a code
note the extra 0 on every step

Run Length Encoding RLE/RLC
□ Quelltext w: Agggbbheffgggg => |w|=15
□ Codiert w_k: A3g2beh3f4g => |w_k|=11
A+3xg+2xb+e+h+3xf+4xg
shortening of length by compressing repetition.

Encoder and Decoder
You need to either choose 1 or 0 as the starting bit. After that the decoder can print out the correct code.
Chiffre text
You can "encrypt" your data by shifting the codes by a certain amount.
In the caesar chiffre this is done with the number 4. a -> e
Please do not use this, use RSA or other algorithms.

Errors
p(x_1)=0.5 x_1
p(x_2)=0.5 x_2
p(y_1)=p(x_1) * p + p(x_2) * (1-q)
p(y_2)=p(x_1) * (1-p) + p(x_2) * (q)
p(y|x) = [p 1-p; 1-q q] → [Σ=1; Σ=1]
1-p and 1-q are the chance for error. Which we of course have to take into account.
p(x_1)=0.5 x_1
p(x_2)=0.25 x_2
p(x_3)=0.25 x_3
p(y_1)=p(x_1) * p(x_1) + p(x_2) * p(x_2) + p(x_3) * p(x_3)
p(y_2)=p(x_1) * p(x_2) + p(x_2) * p(x_2) + p(x_3) * p(x_2)
p(y_3)=p(x_1) * p(x_3) + p(x_2) * p(x_3) + p(x_3) * p(x_3)
p(y|x) = [0.95 0.025 0.025; 0.025 0.95 0.025; 0.025 0.025 0.95]
[0.4875 0.25625 0.25625; 0.5 0.5 0.5; 0.5 0.5 0.5]
